

Deep Dive: 4. Strings in Depth

Concept Summary

Strings are sequences of characters. In Python, they are immutable and can be manipulated using slicing and formatting.

Coding Structure

```
f'text {variable}' OR string[start:end]
```

Example Code

```
word = 'Python'
print(word[0:2])

age = 30
print(f'I am {age} years old.')
```

Code Explanation

- Line 2: Slices the string from index 0 up to (but not including) index 2. This prints 'Py'.
- Line 5: Uses an f-string (formatted string literal) to inject the 'age' variable directly into the text.

Practice Problems

1. Create a string 'Hello World' and slice it to print just 'World'.
2. Use an f-string to print a sentence containing three different variables (name, city, hobby).
