

Deep Dive: 9. Dictionaries

Concept Summary

Dictionaries store data in Key-Value pairs. They are unordered and mutable.

Coding Structure

```
my_dict = {'key': 'value'}  
my_dict['new_key'] = 'new_value'
```

Example Code

```
user = {'name': 'John', 'age': 30}  
user['email'] = 'john@test.com'  
print(user.get('phone', 'No phone'))
```

Code Explanation

- Line 1: Creates a dictionary with two key-value pairs using curly braces.
- Line 2: Adds a new key 'email' and assigns it a value.
- Line 3: Uses the .get() method to safely look for the key 'phone'. Since it doesn't exist, it avoids crashing and returns the default value 'No phone'.

Practice Problems

1. Create a dictionary representing a car (make, model, year). Update the year to 2024.
2. Write a loop that iterates through the car dictionary using .items() and prints 'Key: Value'.
