

Deep Dive: 12. *args and **kwargs

Concept Summary

These allow a function to accept any number of positional (*args) or keyword (**kwargs) arguments.

Coding Structure

```
def func(*args, **kwargs):
```

Example Code

```
def total_sum(*numbers):  
    return sum(numbers)  
  
print(total_sum(1, 2, 3, 4))
```

Code Explanation

- Line 1: The asterisk (*) before 'numbers' tells Python to pack all given positional arguments into a Tuple called 'numbers'.
- Line 2: Uses the built-in sum() function to add all numbers in the tuple.
- Line 4: We can pass as many arguments as we want!

Practice Problems

1. Write a function using **kwargs that accepts user details (name, age, city) and prints them nicely.
2. Write a function that uses *args to multiply an unlimited amount of numbers together.
